Logistic Regression

Chang Lu

1 Model

Let $\mathbf{x} \in \mathbb{R}^{s \times n}$ be the inputs, where n is the number of samples; and s is the dimension of each feature vector. The logistic regression model is:

$$\hat{\mathbf{y}} = \sigma \left(\mathbf{x}^\top \mathbf{w} + b \right) \tag{1}$$

$$= \frac{1}{1 + e^{-\left(\mathbf{x}^\top \mathbf{w} + b \right)}}. \tag{2}$$

Here, $\mathbf{w} \in \mathbb{R}^s$ is the weight. $b \in \mathbb{R}$ is the bias. For an input sample $\mathbf{x}_i$, let y_i be the ground-truth for $\mathbf{x}_i$. The prediction $0 < \hat{y}_i < 1$ is the probability $p\left(y_i = 1 \mid \mathbf{x}_i \right)$.

2 Objective Function

Typically, the logistic regression is a binary classification. Therefore, we use a binary cross-entropy loss as the objective function. For an input sample $\mathbf{x}_i$, the binary cross-entropy loss $L(\mathbf{x}_i, y_i \mid \mathbf{w})$ is:

$$L(\mathbf{x}_i, y_i \mid \mathbf{w}) = -\left(y_i \log \hat{y}_i + (1 - y_i) \log (1 - \hat{y}_i) \right) \tag{3}$$

$$= -\left(y_i \log \left(\frac{1}{1 + e^{-\left(\mathbf{x}_i^\top \mathbf{w} + b \right)}} \right) + (1 - y_i) \log \left(\frac{e^{-\left(\mathbf{x}_i^\top \mathbf{w} + b \right)}}{1 + e^{-\left(\mathbf{x}_i^\top \mathbf{w} + b \right)}} \right) \right) \tag{4}$$

$$= \log \left(1 + e^{-\left(\mathbf{x}_i^\top \mathbf{w} + b \right)} \right) + \left(\mathbf{x}_i^\top \mathbf{w} + b \right) (1 - y_i) \tag{5}$$

For all input samples $\mathbf{x}$, the total loss is an average of the losses for all samples:

$$L(\mathbf{x}, \mathbf{y} \mid \mathbf{w}) = \frac{1}{n} \sum_{i=1}^{n} L(\mathbf{x}_i, y_i \mid \mathbf{w}) \tag{6}$$

$$= \frac{1}{n} \sum_{i=1}^{n} \left(\log \left(1 + e^{-\left(\mathbf{x}_i^\top \mathbf{w} + b \right)} \right) + \left(\mathbf{x}_i^\top \mathbf{w} + b \right) (1 - y_i) \right) \tag{7}$$

3 Back-propagation

$\mathbf{w}$ and b are the only variable in L. Therefore, we only need to calculate the gradient for $\mathbf{w}$ and b:

$$\frac{\partial L}{\partial \mathbf{w}} = \frac{1}{n} \sum_{i=1}^{n} \frac{\partial}{\partial \mathbf{w}} \log \left(1 + e^{-\left(\mathbf{x}_i^\top \mathbf{w} + b \right)} \right) + \frac{1}{n} \sum_{i=1}^{n} \frac{\partial}{\partial \mathbf{w}} \left(\mathbf{x}_i^\top \mathbf{w} + b \right) (1 - y_i) \tag{8}$$

$$= \frac{1}{n} \sum_{i=1}^{n} \frac{-\mathbf{x}_i e^{-\left(\mathbf{x}_i^\top \mathbf{w} + b \right)}}{1 + e^{-\left(\mathbf{x}_i^\top \mathbf{w} + b \right)}} + \frac{1}{n} \sum_{i=1}^{n} \mathbf{x}_i (1 - y_i) \tag{9}$$

$$= \frac{1}{n} \sum_{i=1}^{n} -\mathbf{x}_i (1 - \hat{y}_i) + \frac{1}{N} \sum_{i=1}^{n} \mathbf{x}_i^\top (1 - y_i) \tag{10}$$

$$= \frac{1}{n} \sum_{i=1}^{n} \mathbf{x}_i (\hat{y}_i - y_i) \tag{11}$$

$$\frac{\partial L}{\partial b} = \frac{1}{n} \sum_{i=1}^{n} (\hat{y}_i - y_i) \tag{12}$$
